Fire Prevention and Risk Assessment

Conducting a Risk Assessment:

Look at your surroundings and look for any hazard that you see that can be an obstacle in case of evacuation, a pile of trash can catch on fire or cans of oils and paint right next to an outlet.

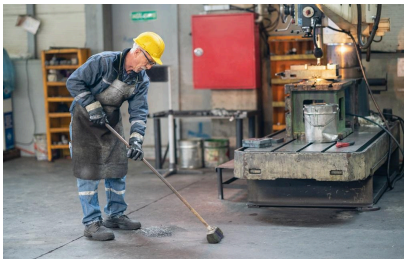

Safe Storage:

Proper storage is crucial for isolating flammable materials from ignition sources.

- Keep minimal amounts: Store only the minimum amount of flammable materials necessary.
- Keep it secure; make sure it will be in a secure place where children cannot reach it.
- Use proper containers: Always store flammable liquids in their original, tightly-sealed, labeled containers.
- Store away from heat: Keep flammable materials away from heat sources, direct sunlight, and open flames.
- Ensure ventilation: Storage areas should be well-ventilated to prevent the buildup of flammable vapors.
- Handle oily rags with care: Oil-soaked rags can spontaneously ignite as they dry. Store them in a tightly-sealed, metal container filled with a water and detergent solution to neutralize the oils before disposal.

Practicing Good Housekeeping:

A clean and organized environment is a fundamental part of fire prevention, it keep the clutter away so that you could move easily when you have to evacuate, and lettering the trash not get piled up ensure they will not become a source of fire along with **proper disposal of combustible material** like **battery, oils, electronic and paints.**

Maintaining Equipment:

Regularly inspect every equipment and appliance in the building, this also includes electrical wiring, light, electrical box, or any fixture that uses electricity. Some of the examples are washing machine and refrigerator, the former since you use it weekly and often gather lint fiber from the clothing it washes that can cause a fire if ignited and the latter since it is constantly using power to keep it self cooled.

Check the light bulb when it starts to flicker to identify the problem and get it fixed.

Any outlet or electrical plug with burn mark, damages, spark or it smelled like burned rubber immediately got it notified to get fixed.

Fire Safety Equipment and Systems

Fire extinguisher

It is important for a person to be properly trained in how to use a Fire Extinguisher. Though fire extinguishers come with directions, these can often be difficult to follow when one is faced with a roaring fire they need to get under control as quickly as possible. If a fire extinguisher is not used properly, it could be ineffective in extinguishing a fire and could even cause injuries.

P - Pull the pin
Remove the safety pin from the handle. This breaks the tamper seal and allows you to discharge the extinguisher.

A - Aim at the base of the fire
Point the nozzle of the extinguisher toward the fuel source at the base of the fire, not at the flames themselves.

S - Squeeze the handle
Press the lever slowly and evenly to discharge the extinguishing agent. Maintain pressure for a continuous stream.

S - Sweep from side to side
Using a slow, sweeping motion, move the nozzle across the base of the fire until it is completely out. Watch the area to ensure the fire does not re-ignite.

Smoke and heat detectors

These devices are your earliest warning system, designed to alert you to a fire before it grows out of control.

How they work:
Smoke detectors: These come in two main types. Ionization detectors sense tiny, invisible products of combustion, making them more sensitive to fast, flaming fires. Photoelectric detectors use a light beam and sensor to detect visible smoke particles, making them more effective at detecting slow, smoldering fires.
Heat detectors: These respond to a significant increase in temperature. They are useful in areas where smoke detectors would be prone to false alarms, such as kitchens, garages, or dusty workshops.

Alarms and Exits

It's important to know where the alarms are along with the exits, so that you can quickly alarm the other of an impending fire in the building and you can quickly evacuate before it gets worse.
